イロン 不得 とくほう 不良 とう

Each surface atom breaks the bonds with its nearest (horizontal) neighbors at a random (exponentially distributed) time and then jumps (uniformly) to one of its neighboring sites.

The rate at which those bonds are broken depends on the energy barrier that must be overcome in breaking them.... but atoms with lots of horizontal neighbors will move infrequently and neighbors with no (adatoms) or few horizontal neighbors will move more frequently.

**Macroscopically** you might expect convex regions to move more slowly than concave regions.

The rate at which those bonds are broken depends on the energy barrier that must be overcome in breaking them.... but atoms with lots of horizontal neighbors will move infrequently and neighbors with no (adatoms) or few horizontal neighbors will move more frequently.

**Macroscopically** you might expect convex regions to move more slowly than concave regions.

We model the crystal surface as an indexed set of integer valued random variables  $h_N(t, \alpha) \in \mathbb{Z}$  where  $\alpha \in \mathbb{T}_N^d$  (the *d*-dimensional torus).

### The jumps:

 $h_N \to J_{\alpha} J^{\beta} h_N$  add an atom at  $\beta$  and subtract one from  $\alpha$ where  $J_{\alpha} h_N(\gamma) = \begin{cases} h_N(\alpha) - 1, & \gamma = \alpha \\ h_N(\gamma), & \gamma \neq \alpha \end{cases}$  and  $J^{\alpha} h_N(\gamma) = \begin{cases} h_N(\alpha) + 1, & \gamma = \alpha \\ h_N(\gamma), & \gamma \neq \alpha \end{cases}$ 

Now we need the rates...

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

We need an estimate of the energy barrier that must be overcome in breaking an atom's neighbor bonds.

If we define the total energy of the surface to be:

$$H(h_N) = \sum_{\alpha \in \mathbb{T}_N} \sum_{i \leq d} V(\nabla_i^+ h_N(\alpha))$$

where

$$abla_i^+ g(\alpha) = g(\alpha + \mathbf{e}_i) - g(\alpha) \quad \text{and} \quad 
abla_i^- g(\alpha) = g(\alpha) - g(\alpha - \mathbf{e}_i)$$

then the (symmetrized) change in energy that results from removing the atom at site  $\alpha$  :

$$n_{\alpha}(h_{N}) = \frac{1}{2} \sum_{i \leq d} \left( V(\nabla_{i}^{+} J_{\alpha} h_{N}(\alpha)) - V(\nabla_{i}^{+} h_{N}(\alpha)) + V(\nabla_{i}^{-} J_{\alpha} h_{N}(\alpha)) - V(\nabla_{i}^{-} h_{N}(\alpha)) \right).$$

(画) (ヨ) (ヨ)

The rate at which the atom at site  $\alpha$  breaks its bonds and becomes free to move is

$$e^{-2Kn_{\alpha}(h_N)}$$

The rate at which an atom breaks its bonds and moves to any particular neighbor is

$$r_N(\alpha) = \frac{1}{2d}e^{-2Kn_\alpha(h_N)}$$

The generator is

$$\mathcal{A}_N f(h_N) = \sum_{\substack{\alpha, \beta \in \mathbb{T}_N^d \\ |\alpha - \beta| = 1}} r_N(\alpha) \left( f(J_\alpha^\beta h_N) - f(h_N) \right).$$

・ 同 ト ・ ヨ ト ・ ヨ ト

 $h(t, \cdot)$  is reversible with respect to the distribution

$$\rho_N^m \propto \begin{cases} e^{-K \sum_{\alpha \in \mathbb{T}_N} \sum_{i \le d} V(\nabla_i^+ h_N(\alpha))}, & \text{if } \sum_{\alpha \in \mathbb{T}_N} h_N(\alpha) = m \\ 0, & \text{otherwise} \end{cases}$$

with  $m = \sum_{\alpha \in \mathbb{T}_N} h_N(0, \alpha)$ 

Our objective is to characterize the non-equilibrium continuum (large N) behavior of the surface.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

# But first...

This is oversimplified but physically reasonable:

The atoms mostly jiggle around on their sites but eventually climb out of the potential well (from bonds with neighbors) confining them. The escape event is rare and it's reasonable to assume that

- the rate is dominated by the change in energy and
- the projection of the system onto the site occupation number remains Markovian.

## A couple of examples

• Suppose 
$$V(z) = |z|$$
. Then

$$n_{lpha}(h_N)+2^{d-1}=\sum_{\substack{eta\in\mathbb{T}_N^d\ |lpha-eta|=1}}\mathbf{1}_{(h_N(lpha)\leq h_N(eta))},$$

i.e. up to an additive constant (a time rescaling), the generalized coordination number is the number of bonds that need to be broken to free the atom at lattice site  $\alpha$ .

**2** Suppose 
$$V(z) = z^2$$
. Then

$$n_{\alpha}(h_N) - 2d = \sum_{i \leq d} \nabla_i^+ h_N(\alpha) - \nabla_i^- h_N(\alpha),$$

i.e. up to an additive constant, the generalized coordination number is the discrete Laplacian of the surface at lattice site  $\alpha$ .

<回> < 回> < 回> < 回>

# Why this model?

This model is far from perfect:

- no substrate interactions (e.g. elasticity),
- Ino defects (e.g. vacancies),
- many systems require modeling the electronic structure (probably via DFT) to get correct barrier heights for estimating jump rates,
- **(4)** . . .

But it is close to models used in very large scale simulations.

These models have not been considered by mathematicians but close relatives have been studied:

Funaki and Spohn (1997) studied the hydrodynamic limit of

$$dh_N(t, lpha) = -rac{\partial H(h_N)}{\partial h_N(lpha)} dt + \sqrt{2K^{-1}} dW(t)$$

where here  $h_N(t, \alpha) \in \mathbb{R}$ 

▲御▶ ▲理▶ ▲理▶ …

They show that if

$$\bar{h}_N(t,x) = N^{-1}h_N(N^4t,\alpha)$$
 where  $Nx \in \bigcap_{i=1}^d \left[ \alpha_i - \frac{1}{2}, \alpha_i + \frac{1}{2} \right)$ 

then  $\bar{h}_N$  converges to the solution of the PDE

$$\partial_t h = K \operatorname{div} \left[ \sigma_C (\nabla h) \right]$$

The surface tension is defined by  $\sigma_{\mathcal{C}}(u) = \nabla \mathcal{F}_{\mathcal{C}}(u)$  where

$$\mathcal{F}_{C}(u) = \frac{1}{K} \sup_{\sigma \in \mathbb{R}^{d}} \left\{ \sigma^{\mathsf{T}} u - \log \int_{w \in \mathbb{R}^{d}} e^{-K \sum_{i \leq d} V(w_{i}) + K \sigma^{\mathsf{T}} w} dw \right\}$$
$$u = \frac{\int w e^{-K \sum_{i \leq d} V(w_{i}) + K \sigma(u)^{\mathsf{T}} w} dw}{\int e^{-K \sum_{i \leq d} V(w_{i}) + K \sigma(u)^{\mathsf{T}} w} dw}$$

▲□▶ ▲□▶ ▲目▶ ▲目▶ 三目 - のへで

Nishikawa (2002) extended Funaki and Spohn's approach to

$$dh(t,\alpha) = \Delta \frac{\partial H(h)}{\partial h(\alpha)} dt + \sqrt{-2K^{-1}\Delta} dW(t)$$

where

$$\Delta \boldsymbol{g}(lpha) = \sum_{i \leq \boldsymbol{d}} 
abla_i^+ \boldsymbol{g}(lpha) - 
abla_i^- \boldsymbol{g}(lpha).$$

He proved that  $\bar{h}_N$  converges to the solution of the PDE

$$\partial_t h = -K\Delta \left[ \operatorname{div} \left[ \sigma_C(\nabla h) \right] \right]$$

▲ □ ▶ ▲ □ ▶ ▲ □ ▶ □ □ ● ○ ○ ○

Recent work of Armstrong-Wu (2019) shows that  $\sigma_C \in C^{2,\beta}$  for some  $\beta > 0$ . What can we say about  $\sigma_D$ ??

This last overdamped Langevin equation for continuous height variables can be derived from the KMC model by introducing a vanishing lattice constant.

Replace V(z) by V(az), rescaling time appropriately, and taking  $a \rightarrow 0$ .

One can then apply Nishikawa's result to make an approximate statement about the scaling limit of the KMC equations.

This was pointed out by Haselwandter and Vvedensky.

イロト 不得 とくき とくきとうき

The small lattice constant limit sacrifices interesting features.

For example, if *V* is symmetric and if  $h_N$  is a solution of the SDE then  $-h_N$  is also a solution.

Remember that in the KMC model convex regions are much stickier than concave regions.

・ 同 ト ・ ヨ ト ・ ヨ ト ・

Krug, Dobbs, and Majaniemi studied the evolution of a model very similar to our KMC models in 1D when V(z) = |z|

They first argue for

$$\partial_t h = -K\Delta \left[ \operatorname{div} \left[ \sigma_D(\nabla h) \right] \right]$$

with  $\sigma_D(u) = \nabla \mathcal{F}_D(u)$  where

$$\mathcal{F}_{D}(u) = \frac{1}{K} \sup_{\sigma \in \mathbb{R}^{d}} \left\{ \sigma^{\mathsf{T}} u - \log \sum_{z \in \mathbb{Z}^{d}} e^{-K \sum_{i \leq d} V(z_{i}) + K \sigma^{\mathsf{T}} z} \right\}$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Then at the end of the paper they give arguments supporting

$$\partial_t h = \Delta \left[ e^{-K \operatorname{div}[\sigma_D(\nabla h)]} \right]$$

As they point out... this PDE gives the first PDE when curvature of the surface is small.

M-Weare (2013): The correct limit depends on the scaling regime.

And the standard scaling regime may tell us less about the physics.

In the  $h \sim N^{-1}h_N$ ,  $s \sim N^4 t$ ,  $x \sim N^{-1}\alpha$  regime we argue for

$$\partial_t h = -\frac{K}{2d} \Delta \left[ \operatorname{div} \left[ \sigma_D(\nabla h) \right] \right]$$

Figure:  $V = z^2$  for T = 1e - 1 at K = 1.5

In the  $h \sim N^{-1}h_N$ ,  $s \sim N^4 t$ ,  $x \sim N^{-1}\alpha$  regime we argue for

$$\partial_t h = -\frac{K}{2d} \Delta \left[ \operatorname{div} \left[ \sigma_D(\nabla h) \right] \right]$$

Figure: V = |z| for T = 1e - 3 at K = 1.5

Now suppose that for some p > 1

$$V(\kappa u) = \kappa^{p} V(u)$$
 for all  $\kappa > 0$ 

Letting  $q = rac{p}{p-1}$  and scaling like

$$h \sim N^{-q} h_N$$
  $s \sim N^{q+2} t$   $x \sim N^{-1} \alpha$ 

we argue that  $\bar{h}_N$  converges to the solution of

$$\partial_t h = \frac{1}{2d} \Delta \left[ e^{-K \sum_{i \leq d} V'(\partial_{x_i} h) \partial_{x_i}^2 h} \right]$$

Figure: 
$$V = |z|^{3/2}$$
 for  $T = 1e - 12$  at  $K = 1.5$ 

Figure:  $V = z^2$  for T = 1e - 20 at K = 1.5

- For the rough pde with p = 1 and the continuous surface tension, jointly with Jian-Guo Liu, Jianfeng Lu and Dio Margetis (2019) we derived the exponential PDE in the p = 1 case and studied facet dynamics for that model. This is related to the work of Giga-Kohn (2011), Giga-Giga (2010) on Total Variation flows.
- The PDE takes the form

$$\partial_t h = \partial_{xx} e^{-\partial_x \left(\frac{\partial_x h}{|\partial_x h|}\right)}, \quad h(x,0) = h_0(x),$$

 One can even include 2nd order effects of evaporation and deposition to arrive at at PDE of the form:

$$\partial_t h = \Delta e^{-\Delta h} + (1 - e^{-\Delta h}).$$

See Gao-Liu-Lu-M (2020).

Define

$$u:=e^{-\Delta h}.$$

The equation can be formally recast as

$$\partial_t u = -u\Delta[\Delta u + (1-u)].$$

 For weak solutions, use a regularized method to first prove the existence and strict positivity for regularized solution *u*<sub>ε</sub> to a properly modified equation below, then take limit ε → 0. For 0 < α < 1, the regularization of the *u* equation we consider is

$$\begin{cases} \partial_t u_{\varepsilon} = -\frac{u_{\varepsilon}^{1+\alpha}}{u_{\varepsilon}^{\alpha} + \varepsilon^{\alpha}} (\partial_x^4 u_{\varepsilon} - \partial_x^2 u_{\varepsilon}), & \text{for } t \in [0, T], \ x \in \mathbb{T}; \\ u_{\varepsilon}(0, x) = u_0(x) + \varepsilon, & \text{for } x \in \mathbb{T}. \end{cases}$$

• Note, setting  $v = u_x$ , we get

$$\partial_t \mathbf{v} = \mathbf{v} \mathbf{v}_{\mathbf{x}} + \mathbf{u} \mathbf{v}_{\mathbf{x}\mathbf{x}},$$

1

which resembles an Euler equation with variable coefficient viscosity. It was observed by Tarek Elgindi that using the maximum principle this solution cannot form a true singularity. With David Ambrose and Doug Wright, we are now pursuing this as a means of capturing both the transition layer between self-similar profiles and trying to build solutions that almost form singularities in the 2nd order case and do indeed form singularities in the 4th order problem.

With Yuan Gao, Jian-Guo Liu, Jianfeng Lu and Anya Katsevich (2021), we considered Metropolis-style rates and analyzing dynamics in comparison to the Adatom KMC models. These rates have some distinct differences and a temperature dependence in the form of the limiting PDEs can be seen. We focus here on the case p = 2 as many calculations become more explicit. The PDE limit proposed here is of the form

$$\partial_t h(t, \mathbf{x}) = \partial_{\mathbf{x}} \left( e^{\left[ -\partial_{\mathbf{x}}^3 h(t, \mathbf{x}) \right]} - e^{\left[ \partial_{\mathbf{x}}^3 h(t, \mathbf{x}) \right]} \right).$$

• This is NOT quite the exact limit you get from the KMC system, but it is close as the temperature gets large. See the works by Katsevich exploring this (2022,2023).

• Recall, we are generally interested in the models we consider of the form:

$$h_t = \Delta e^{-\Delta_{
ho} h}$$

for  $\Delta_p$  the *p*-Lapalcian for  $p \ge 1$  given by the Euler-Lagrange equation for the surface energy

$$E(h)=\frac{1}{p}\int |\nabla h|^p dx.$$

イロト 不得 とくほ とくほとう

э

 Recently, with Craig, Liu, Lu and Wang, we have introduced a gradient flow structure numerical flow that allows one to numerically solve

$$h_t = \Delta e^{-\Delta_1 h}$$

using the FORMAL gradient flow structure

$$h_t + \nabla \cdot \left( M(h) \nabla \frac{\partial \mathcal{E}}{\partial h} \right) = 0,$$
  
$$M(h) = e^{-\Delta_1 h}, \ \mathcal{E}(h) = \|\nabla h\|_{L^1}.$$

$$h^{m+1} = \left(\frac{\tau}{\lambda}\Delta_{h^n}\Delta + I\right)^{-1} \left(\frac{\tau}{\lambda}\Delta_{h^n}\Delta h^{(m)} - \tau\Delta_{h^n}\nabla\cdot\phi^{(m)} + h^n\right),$$
  
$$\overline{h}^{(m+1)} = 2h^{(m+1)} - h^{(m)},$$
  
$$\phi^{(m+1)} = (I + \sigma\partial F^*)^{-1}(\phi^{(m)} + \sigma\nabla\overline{h}^{(m+1)})$$

where

$$(I + \sigma \partial F^*)^{-1}(u(x)) = \min\{u(x), 1\} \operatorname{sign}(u(x)).$$

We do not invert the 1-Laplacian!

$$(D^tD + \frac{\lambda}{\tau}A^{-1}(\cdot - h^n))^{-1} = (\frac{\tau}{\lambda}AD^tDu + h^n).$$

• Can choose  $\lambda$  quite large!

We do not invert the 1-Laplacian!

$$(D^tD+\frac{\lambda}{\tau}A^{-1}(\cdot-h^n))^{-1}=(\frac{\tau}{\lambda}AD^tDu+h^n).$$

Can choose λ quite large!

• Let d = 1. Suppose the PDHG algorithm is initialized with

$$h^{(0)} = h^n, \ \phi^{(0)} = 0, \ \text{ where } \ \mathcal{E}(h^n) < \infty.$$

Then for all  $\delta > 0$ , there exist  $\tilde{M}, \lambda, \sigma$  such that

$$F(h^{(M)}-F(h^{n+1})\leq \delta, \ \forall M\geq \tilde{M}, \ F(h)=\mathcal{E}(h)+\frac{1}{2\tau}\|h-h^n\|_{H^{-1}_{h^n}}^2.$$

### Remarks

- Extends to general *M*(*h*) provided *M*(*h<sup>n</sup>*), 1/*M*(*h<sup>n</sup>*) ∈ *L*<sup>1</sup> (Cancés-Gallouët-Todeschi (2019)).
- The restriction d = 1 is to apply a Sobolev embedding. Different integrability on 1/M required to go to higher dimensions.
- If  $\nabla h^n \in BV$ , the estimates are quantitative:  $\tilde{M} \sim \delta^{-2}, \lambda \sim \delta^{-1}, \sigma \sim \delta$ .

$$\min_{\|h^n-h\|_{\mathcal{H}}\leq R}(F(h)-F(h^{n+1}))\to 0$$

as  $R \to \infty$ .

#### Numerical Results: energy decrease

イロト 不得 とくき とくき とうきょう

#### Numerical Results: convergence

Observations:

- Error vs Nx: slightly sublinear convergence (low spatial regularity)
- Error vs Nt: first order (semi-implicit Euler)
- Internal time steps vs Nt: importance of selecting correct Hilbert space

sinusoidal, (Nx = 200), (Nt = 10),  $\sigma$  = 0.0005,  $\lambda$  = 500,  $\epsilon$  =0.05, T = 10<sup>-4</sup>

Basic questions remain unanswered:

- Can we prove that the exponential PDE has a solution (in some space) for other *p* values, especially *p* = 1?
- ② Can we prove convergence of the microscopic model to the PDE in our scaling regimes? See recent work of Katsevich!
- Ocan we establish finite time singularity formation in the 2nd derivative in the case p = 2?
- I Full global strong solutions with g > 0? Convergence of dynamics as g → 0?

There are also lots of great questions about the qualitative behavior that can be asked w.r.t. wetting and self-similarity.
